### *Verrucariopsis* Gueidan, Monnat & Cl. Roux

The genus *Verrucariopsis* was established by Gueidan et al. (2022) to accommodate *V. suaedae* as the type species that grows on the stems of *Suaeda vera* collected from the coast of Brittany and Loire-Atlantique in France. The genus is characterized by a crustose thallus with green algae (*Chlorophyta*), perithecioid globous semi-immersed ascomata, an excipulum covering the upper half of the ascomata, hamathecium consisting of periphyses and short pseudoparaphyses of type b (follow Roux & Triebel 1994), a hymenium with J+ (orange-red) coloration, bitunicate 8-spored ascospores, and aseptate, hyaline, globous ascospores. Conidiomata are pycnidiod, multi-chambered with short bacilliform conidia. Based on the analysis of multigene (nuLSU, nuSSU, mtSSU, and *RPB1*) sequence data, Gueidan et al. (2022) demonstrated that the genus *Verrucariopsis* forms a well-supported clade and includes two species, *V. suaedae* and *V. halophila*. The genus exhibits a sister relationship to the marine lichen genera *Mastodia* and *Wahlenbergiella*, as well as to the single sequence of *Verrucaria halizoa* and several *Verrucaria* specimens with uncertain identification. The taxonomic placement of *Verrucariopsis* is within *Verrucariaceae* (*Verrucariales*, *Eurotiomycetes*).
